

RF Detector/Controller

PRODUCT DESCRIPTION

The MS2351M/MS2351D is a logarithmic amplifier chip, which is mainly used for receiving signal strength indication (RSSI) and controlling power amplifier. Its operating frequency ranges from 0.05GHz to 4.0GHz. Dynamic range can reach from 35dB to 45dB.

The MS2351M/MS2351D is a voltage response device. When it operates in the frequency range of 0.05GHz to 2.5GHz, the root mean square value of typical input signal ranges from 1.25mV to 224mV or from -45dBm~0dBm@50Ω.

AC coupling is used internally in the MS2351M/MS2351D to provide two kinds of output voltage. One is from V_UP pin. The other one is from V_DN pin, which is the reverse phase of V_UP voltage and twice the gain. V_DN output drops from 2.20V to close to ground, which makes the chip operate in control mode.

MSOP8

DFN8

FEATURES

- Complete RF Detector/ Controller Function
- Dynamic Range in Typical Conditions:
0.05GHz~2.5GHz: -45dBm~0dBm@50Ω
2.6GHz~3.0GHz: -40dBm~0dBm@50Ω
3.1GHz~4.0GHz: -35dBm~0dBm@50Ω
- 10dB Step Response Time: 83ns
- Good Temperature Stability
- Single Power Supply: 2.7V~5.5V

APPLICATIONS

- Reception of Wireless Terminal and TSSI
- Power Measurement and Control of Transmitter

PRODUCT SPECIFICATION

Part Number	Package	Marking
MS2351M	MSOP8	MS2351M
MS2351D	DFN8	2351D

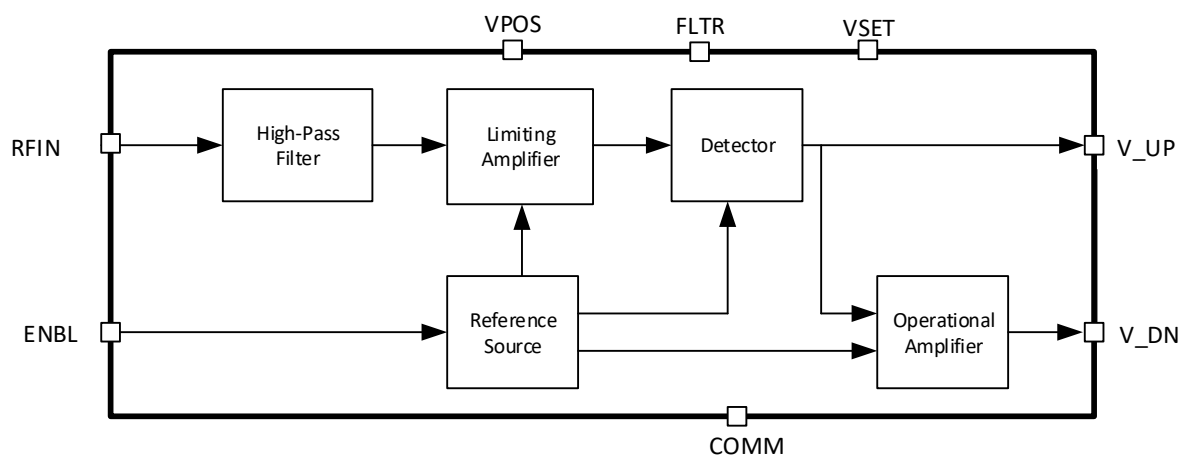

PIN CONFIGURATION

PIN DESCRIPTION

Pin	Name	Type	Description
1	RFIN	I	RF Input
2	ENBL	I	Connected to Power Supply: Normal Operation Mode. Connected to Ground: Shutdown.
3	VSET	I	Set the voltage for operating in control mode, VSET is connected to V_UP for operating in measurement mode.
4	FLTR	O	Connected with the external capacitor to extend output response time. The capacitor is connected between FLTR and V_UP
5	COMM	-	Reference Ground
6	V_UP	O	Logarithmic Output. Output is proportional to input signal amplitude
7	V_DN	O	Reverse Phase of V_UP. Relationship: $V_{DN}=2.20-2 \times V_{UP}$
8	VPOS	-	Power Supply

BLOCK DIAGRAM

ABSOLUTE MAXIMUM RATINGS

Any exceeding absolute maximum rating application causes permanent damage to device. Because long-time absolute operation state affects device reliability. Absolute ratings just conclude from a series of extreme tests. It doesn't represent chip can operate normally in these extreme conditions.

Parameter	Symbol	Range	Unit
Power Supply	VPOS	5.5	V
V_UP, V_DN, VSET, ENBL		0 ~ V _{POS}	V
Input Voltage		1.6	V rms
Equivalent Power		+17	dBm
Maximum Allowable Power Dissipation	P _D	200	mW
Operating Temperature ¹	T _{opr}	-40 ~ +85	°C
Storage Temperature	T _{stg}	-55 ~ +150	°C
Lead Temperature (10s)	T _{TOR}	260	°C

Note 1: Actual operating temperature range is relative to operating frequency.

ELECTRICAL CHARACTERISTICS

Unless otherwise noted, VCC=3.3V, TA = 25°C., .

Parameter	Condition	Min	Typ	Max	Unit
Overall Characteristics	45dB Dynamic Range	0.05		2.5	GHz
	40dB Dynamic Range	2.6		3.0	GHz
	35dB Dynamic Range	3.1		4.0	GHz
Input Voltage	Internal AC Coupling	1.25		224	mV rms
Equivalent Power	External Terminal of 51Ω, 0.05GHz~2.5GHz	-45		0	dBm

FUNCTION DESCRIPTION

In order to easy to understand and calculate, logarithmic amplifier is often expressed as follows:

$$V_{UP} = V_{slope} \cdot \log\left(\frac{V_{IN}}{V_X}\right)$$

V_{slope} - Logarithmic Slope

V_X - Logarithmic Intercept

V_{IN} - Input Voltage

V_{UP} -Signal Strength Indication Output Voltage

Replacing input voltage with power, the equation can be further rewritten as:

$$V_{UP} = V_{SLOPE} \cdot (P_{IN} - P_O)$$

This formula is also the bias for calculating theoretical output.

Where, V_{SLOPE} is the logarithmic slope, P_{IN} is the input power (@50Ω, dBm), P_O is the logarithmic intercept. V_{SLOPE} and P_O are constants, output voltage and input signal power(dBm) are linear relationship.

The factual error is defined as the difference between factual output and theoretical output.

$$Error(dB) = \frac{V_{UP} - V_{slope} \times (P_{IN} - P_O)}{V_{slope}}$$

dBV can be used as a unit instead of dBm. Because dBV compression is fixed without depending on terminal impedance. But dBm depends on terminal load impedance. Take the root-mean-224mv sine wave as an example, it is expressed as fixed -13dBV, which corresponds to 0dBm@50Ω. In specified 50Ω system, 0dBV=+13dBm.

The MS2351 also includes a reverse amplification output function, which can be used in control mode. Most power amplifiers require a gain control bias circuit that must be able to change from a large positive value to ground when the power output requirement is reduced. V_{DN} pin of the MS2351 can generate this control voltage. The voltage not only has the opposite polarity to V_{UP} , but also must have certain DC offset to determine the maximum positive value corresponding to input signal power.

The initial value of V_{DN} is about 2.2V and decreases by twice the V_{UP} slope.

The relationship between V_{DN} and V_{UP} is as follows:

$$V_{DN} = 2.20 - 2 \times V_{UP}$$

The Relationship between V_{DN} and V_{UP}

APPLICATIONS

1. Measurement Mode

Figure 1 shows the connection relationship in measurement mode. A 0.1μF decoupling capacitor should be connected close to pin VPOS. If necessary, a small resistor or a inductor can be connected in series between external power supply and VPOS pin to further reduce power noise. When in normal operating mode, ENBL is connected to VPOS; When ENBL is connected to ground, the chip is shutdown.

When in measurement mode, VSET is connected to V_UP. This feedback path sets logarithmic slope at the usual value. At 1900MHz, the peak voltage ranges from -58dBV to -13dBV. Therefore, equivalent power ranges from -45dBm to 0dBm with 50Ω terminal.

V_DN is not usually used when in measurement mode.

Filter Capacitor

The video signal bandwidth of V_UP and V_DN is about 3.5MHz. In the sinusoidal signal application, when input signal frequency is much higher than 3.5MHz, there is no need to further filter the demodulation signal. When used in low-frequency carrier amplitude modulation application, the low-pass angle frequency needs to be reduced by increasing external capacitor C_F (Figure 1). The video signal bandwidth is calculated as follows:

$$BW = \frac{1}{2 \times \pi \times 4.4k\Omega \times (10pF + C_F)}$$

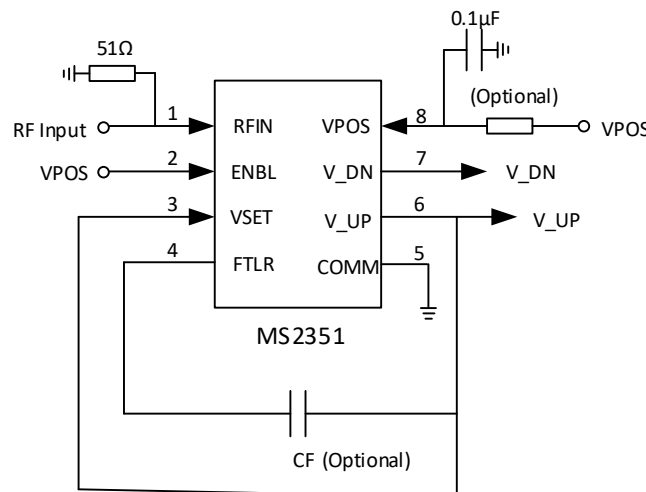

Figure 1. Basic Connections in Measurement Mode

2. Control Mode

Figure 2 shows the basic connections in control mode. Figure 3 shows typical application. The feedback from V_UP to VSET is broken, and the desired voltage is applied to VSET pin. When the signal power of RFIN is less than VSET voltage, V_DN would output high; When the signal power of RFIN is slightly higher than VSET voltage, V_DN would rapidly decrease to close to ground. However, in this closed loop, the reduction of V_DN causes the power amplifier to reduce its output. Finally, the actual signal power of input terminal of the MS2351 reaches a balance with the voltage required by VSET pin. The relationship between

input signal and the voltage set by VSET pin follows the transmission function of the MS2351 (input signal amplitude VS. V_UP).

For example, when VSET=1, the input signal power 0dBm on RFIN is required. Correspondingly, the output power of power amplifier should be more than 0dBm due to the attenuation of antenna coupler.

As shown in Figure 3, when the MS2351 is applied in the control loop of power amplifier, V_UP can set needed response time through the use of optional C_F. The transient response is determined by filter capacitance C_F. When C_F is large, this loop is stable unconditionally, but the response is slower. The minimum capacitance C_F should be used so that the loop can be stabilized. And the specific power amplifier is required for controlling function attenuation. Because of the unavoidable nonlinearity, the choice of C_F must consider the worst case, which usually occurs at the minimum output of the power amplifier. Usually, resistor can be connected in series with C_F to increase a zero point to improve the dynamic characteristics of the loop.

Figure 2. Control Mode

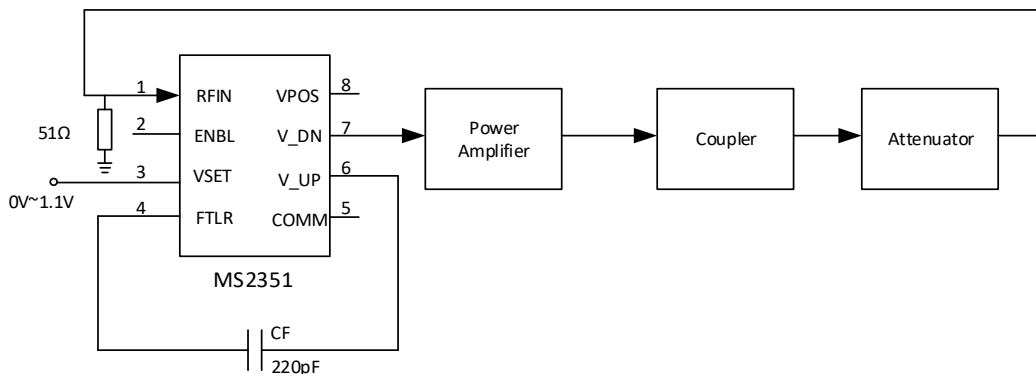

Figure 3. Typical Application in Control Mode

The voltage on VSET pin of the MS2351 ranges from 0V to 1.1V. Typically, it is driven by digital-to-analog converter (DAC). The voltage is compared with the input signal of the MS2351. Any unbalance between VSET and RF input would be calibrated by V_DN (gain control pin of power amplifier is driven by V_DN).

Filter capacitor must be used to make the loop stable. The choice of C_F depends on gain control of power amplifier. But its frequency characteristic is very bad, so some tests and errors are unavoidable. In the example, 220pF capacitance gives enough speed for this loop so as to meet the slot time requirement while its response is still stable.

3. Input Coupling Options

The MS2351 has an internal input coupling capacitor without external AC coupling resistor. Figure 4 shows match networks of narrowband, broadband and attenuator. Smith Circle can be used in actual need for match to ensure the best component value.

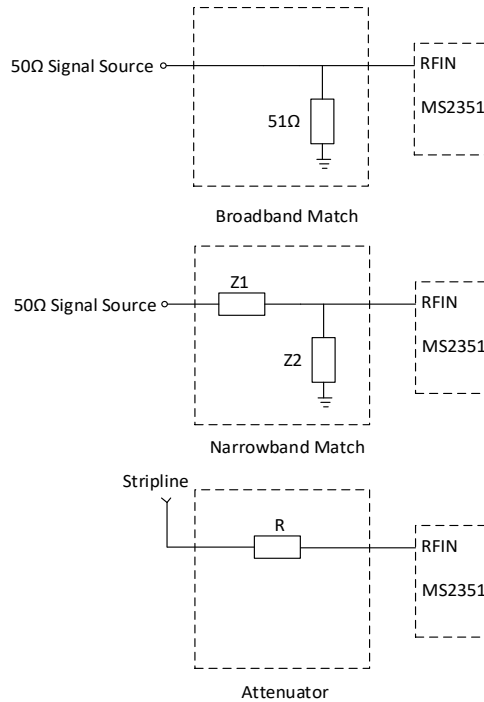

Figure 4 . Input Match and Connections

4. Increase Logarithmic Slope in Control Mode

The logarithmic slope can be increased by the connection method in Figure 5 to meet the maximum V_UP value, but available dynamic range will be reduced accordingly. In fact, the application environment should be considered.

Figure 5. Increasing Output Logarithmic Slope

The value of R1/R2 is determined by the following formula:

$$\frac{R1}{R2} = \frac{Slope_{new}}{Slope_{old}} - 1$$

If two equivalent resistors are used (both resistance values should be larger than 5kΩ), the logarithmic slope becomes twice the origin.

5. Evaluation Board

Figure 6 shows the evaluation board of the MS2351, The circuit is powered by single 2.7V~5.5V power supply. The power supply is decoupled by 0.1μF capacitance. For further decoupling, a resistor R5 or an inductor can be added.

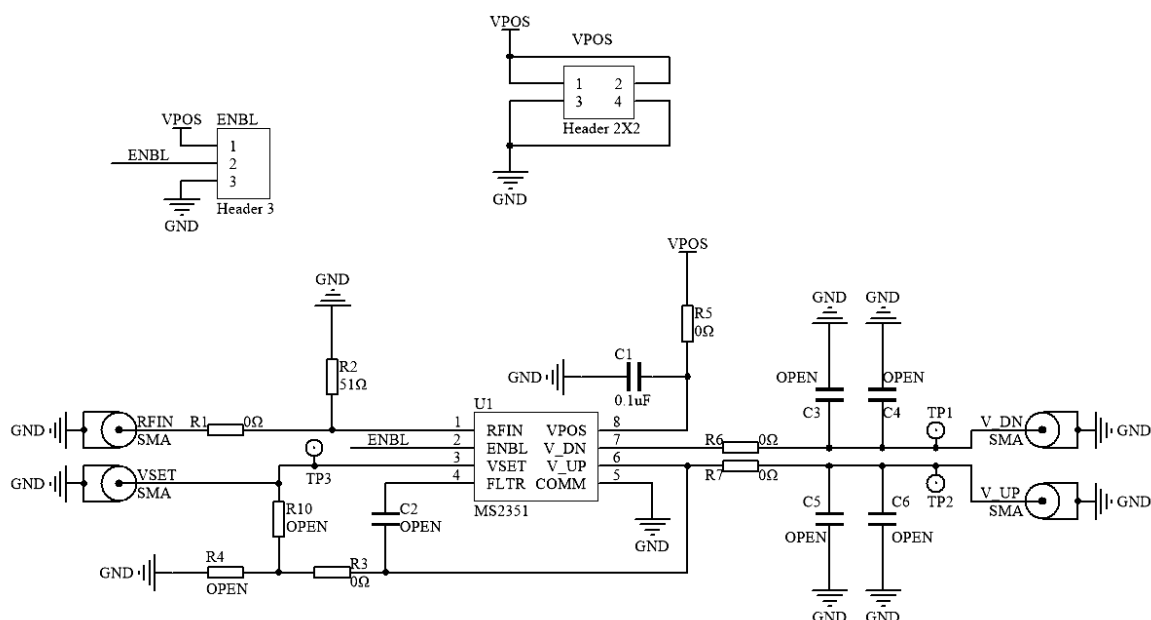

Figure 6. The MS2351 Evaluation Board

STATEMENT

- All Revision Rights of Datasheets Reserved for Ruimeng. Don't release additional notice.
Customer should get latest version information and verify the integrity before placing order.
- When using Ruimeng products to design and produce, purchaser has the responsibility to observe safety standard and adopt corresponding precautions, in order to avoid personal injury and property loss caused by potential failure risk.
- The process of improving product is endless. And our company would sincerely provide more excellent product for customer.

**MOS CIRCUIT OPERATION PRECAUTIONS**

Static electricity can be generated in many places. The following precautions can be taken to effectively prevent the damage of MOS circuit caused by electrostatic discharge:

1. The operator shall ground through the anti-static wristband.
2. The equipment shell must be grounded.
3. The tools used in the assembly process must be grounded.
4. Must use conductor packaging or anti-static materials packaging or transportation.
